## Definitions of vulnerability classification

### **CRITICAL**

Bug / Logic failures in the code that cause loss of assets / data manipulation.

### **HIGH**

Difficult to exploit problems which could result in elevated privileges, data loss etc.

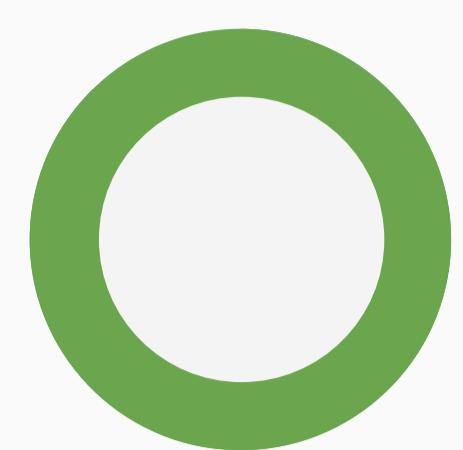

### **MEDIUM**

Bug / Logic failures in the code which need to be fixed but cannot lead to loss of assets / data manipulation.

### **LOW**

Mostly related to unused code, style guide violations, code snippets with low effect etc.

## Findings

0  
Critical

0  
High

0

## Summary

|        |                                                                      |                  |                           |
|--------|----------------------------------------------------------------------|------------------|---------------------------|
| Cov-01 | Create modifiers for common require statements                       | <span>Low</span> | <span>Fixed</span>        |
| Cov-02 | Missing validation in getValidatorCompoundedStakingData()            | <span>Low</span> | <span>Acknowledged</span> |
| Cov-03 | No zero address check                                                | <span>Low</span> | <span>Fixed</span>        |
| Cov-04 | Extract the length of the array defaultToBurn in a separate variable | <span>Low</span> | <span>Fixed</span>        |
| Cov-05 | Gas inefficiency                                                     | <span>Low</span> | <span>Acknowledged</span> |

## Finding: Cov-01

Create modifiers for common require statements

|      |          |                         |          |                                          |                                            |
|------|----------|-------------------------|----------|------------------------------------------|--------------------------------------------|
| Base | Function | _burnDelegatorBalance   | Line 127 | <span style="color: green;">●</span> Low | <span style="color: green;">✓</span> Fixed |
| Base | Function | getValidatorStakingData | Line 196 | <span style="color: green;">●</span> Low | <span style="color: green;">✓</span> Fixed |
| Base | Function | getDelegatorMetadata    | Line 218 | <span style="color: green;">●</span> Low | <span style="color: green;">✓</span> Fixed |

## Description

The contract contains the same require statement, i.e.

```
require(validatorId < validatorsN, "Invalid validator");
```

used in `getValidatorStakingData`, `getDelegatorMetadata` and `_burnDelegatorBalance` functions. This means that the same code is repeated in multiple functions.

## Recommendation

Create a modifier for the repetitive require statements.

## Finding: Cov-02

Missing validation in `getValidatorCompoundedStakingData()`

Base    Function `getValidatorCompoundedStakingData()`    Line 205 ~ 212    ● Low    ✓ Acknowledged

### Description

There is no validation for checking that the `validatorId` parameter in `getValidatorCompoundedStakingData()` is valid. This means that the function can be called with an invalid `validatorId` value.

### Recommendation

Add a require statement to ensure that `validatorId` is always valid.

## Finding: Cov-03

No zero address check

|      |          |                   |          |                                          |                                            |
|------|----------|-------------------|----------|------------------------------------------|--------------------------------------------|
| Base | Function | setCQTAddress     | Line 168 | <span style="color: green;">●</span> Low | <span style="color: green;">✓</span> Fixed |
| Base | Function | withdrawAllMadCQT | Line 160 | <span style="color: green;">●</span> Low | <span style="color: green;">✓</span> Fixed |

## Description

The `setCQTAddress` and `withdrawAllMadCQT` functions in the contract does not include any checks to verify that the address parameter is not a zero address (0x0). This could potentially be a risk, as sending funds to the zero address would result in the loss of those funds.

## Recommendation

Add require statements to ensure that the address passed to `setCQTAddress` and `withdrawAllMadCQT` functions are valid.

## Finding: Cov-04

Extract the length of the array `defaultToBurn` in a separate variable

Base

Function

burnDefaultDelegates

Line 110

Low

Fixed

### Description

Extract the length of the array `defaultToBurn` used in the condition for the first for loop into a separate variable so that it is not calculated on every loop.

### Recommendation

Create a separate variable for the length of the array used in the for loop.

## Finding: Cov-05

Gas inefficiency

Base

Function

burnDefaultDelegators

Line 101

Low

Acknowledged

## Description

The function `burnDefaultDelegators` has nested loops in its code. These loops can cause inefficiency in the amount of gas needed to execute the function, leading to transaction failure. The inefficiency occurs because each iteration of the loop requires additional gas to be consumed. This can cause the total gas required to execute the function to exceed the gas limit set by the Ethereum network, resulting in the transaction being rejected. It is important to carefully consider the use of loops in Solidity code to avoid potential gas inefficiency and transaction failure.

## Executive Summary

Based on the audit findings the Client's contracts are: Well Secured

 Not Secure     Insufficiently Secured     Secured     Well Secured

## Disclaimers

### SafePress Disclaimer

The smart contracts given for audit have been analyzed by the best industry practices at the date of this report, with cybersecurity vulnerabilities and issues in smart contract source code, the details of which are disclosed in this report (Source Code); the Source Code compilation, deployment, and functionality (performing the intended functions). The audit makes no statements or warranties on the security of the code. It also cannot be considered a sufficient assessment regarding the utility and safety of the code, bug-free status, or any other contract statements. While we have done our best in conducting the analysis and producing this report, it is important to note that you should not rely on this report only – we recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contracts.

### Technical Disclaimer

Smart contracts are deployed and executed on a blockchain platform. The platform, its programming language, and other software related to the smart contract can have vulnerabilities that can lead to hacks. Thus, the audit cannot guarantee the explicit security of the audited smart contracts.
